14 Ways to Say Nothing with Scientific Visualization

A. Globus, Computer Sciences Corporation[1]

E. Raible, NASA Ames Research Center

Scientific visualization can be used to produce beautiful pictures. Those not properly initiated into the mysteries of visualization research often fail to appreciate the artistic qualities of these images. Scientists will frequently use our work to needlessly understand the data from which it is derived. This paper describes a number of effective techniques to confound such pernicious activity.

Introduction

Upon reading D. Bailey's seminal work, "Twelve Ways to Fool the Masses When Giving Performance Results on Parallel Computers,"[1] the authors were struck by the brilliant simplicity of the concept. Bailey ends with the admonition "... conclude your technical presentation and roll the videotape. Audiences love razzle-dazzle color graphics, and this material often helps deflect attention from the substantive technical issues." Unfortunately, Bailey gives no guidance in the means and methods to produce the intended result. This article humbly seeks to fill this void.

There are a number of time-tested scientific visualization techniques for producing pretty pictures while avoiding unnecessary illumination of the data. Our collection has been culled from the scientific visualization literature and numerous presentations the authors have given and attended.

1. Never Include a Color Legend

Many visualization techniques involve assigning colors to scalar data values. In lesser sciences, a legend relating colors to values is provided. In our exalted art form, not only does a legend mar the beauty of an image, but the viewer may be diverted into idle contemplation of reality.

(Note: images can be particularly enthralling if the sequence of colors is chosen solely on aesthetic grounds. For optimal results, quietly use separate color mappings for different parts of the

image.)

2. Avoid Annotation

In dreary old fashioned sciences like physics and biology, investigators have been known to annotate their images with arrows pointing out features of supposed interest along with explanatory text. This promotes clarity of understanding, undermining the sense of awe and confusion the best scientific visualization engenders.

3. Never Mention Error Characteristics

If scientists using visualization software were aware that visualization techniques might introduce error, they might not be properly impressed by our masterworks. Therefore, never imply by word or deed that your algorithm introduces any error whatsoever. After all, if the picture looks good, it must be correct.

4. When in Doubt, Smooth

Always strive for the smoothest possible surfaces, since they look so much better than numerous ugly facets. For example, choose lighting normals to hide sharp edges in the data. Smoothing can also obscure errors and allow users to publish their results earlier.

5. Avoid Providing Performance Data

When you are presenting a pretty picture, some stick-in-the-mud may ask how long it took to calculate. The fact that your ray-cast isosurface took hours of massively parallel supercomputer time to generate when nearly identical results could be achieved using marching cubes[2] in seconds on a workstation is irrelevant. In addition to being smoother (see rule 4), a ray cast image can include some wispy stuff scattered around to give the image an ethereal quality.

6. Quietly Use Stop-Frame Video Techniques

Each frame of a scientific video usually takes seconds, minutes, or even hours to produce. To achieve smooth animation it is usually necessary to generate video frames one at a time and transfer each separately to tape. They can then be played back at 30 or even 60 frames a second. Stop-frame techniques can dramatically improve perceived software performance. The magic is lost,

however, if you are so foolish as to tell anyone what you're doing.

Faithful adherence to the rest of the rules will help avoid tedious debugging of software that already produces pretty pictures.

7. Never Learn Anything About the Data or Scientific Discipline

Debugging scientific visualization software is much more difficult if you are worried about producing correct results. Irritating details like accurate interpolation techniques get in the way; in many cases ad-hoc interpolation techniques can produce much prettier pictures with significantly less work. Better yet, programming bugs can sometimes produce stunning images. If you don't know what to expect, you won't have to find and fix such bugs. As we all know, beauty is the higher truth.

8. Never Compare Your Results with Other Visualization Techniques

Comparison of results with other visualization techniques is fraught with danger. You may detect bugs in your code that will need to be fixed, a tedious chore. Much worse, other techniques may produce prettier pictures.

9. Avoid Visualization Systems

Visualization systems, such as FAST (Flow Analysis Software Toolkit)[3] and AVS (Application Visualization System)[4], provide mechanisms to add modules implementing new visualization techniques. There are two problem with these systems. First, users may violate rule 8 to your discomfort. Second, visualization systems are usually NIH (not invented here).

10. Never Cite References for the Data

If you cite a reference describing the data used to generate images, someone may read the paper and discover that your visualization bears no relationship to the key elements the original experiment was meant to elucidate. This will detract from your picture's appeal and should be avoided.

11. Claim Generality but Show Results from a Single Data Set

It can be difficult to write visualization algorithms that function properly on a variety of data. Much effort may be saved by running your software on one (small) data set and using viewing

angle and color map manipulations to make the images look different, as if from multiple datasets. Follow rule 10 so that no one will know what you're doing.

12. Use Viewing Angle to Hide Blemishes

Many otherwise excellent algorithms produce 3D objects containing unsightly blemishes. Avoid carelessly choosing viewing angles that expose such flaws. If a suitable angle cannot be found, try another data set. If another data set is too much trouble, then:

13. If Viewing Angle Fails, Try Specularity or Shadows

Sometimes every possible viewing angle is marred by some small ugliness. In these cases, try adding shadows or brilliant highlights in appropriate places. However, never resort to using a paint program to touch up your image; that wouldn't be scientific.

14. 'This is easily extended to 3-D'

Three-dimensional algorithms are almost always much more difficult than 2-D and the effort of generalizing a promising 2-D algorithm to 3-D can detract from producing pretty pictures. To both impress your colleagues and avoid much tedious work, simply claim that your algorithm "is easily extended to three or more dimensions." Only the real pros will know you are lying, but they won't challenge you since we all make identical claims.

Conclusion

As Dr. Bailey pointed out, "It is often necessary for us to adopt some advanced techniques in order to deflect attention from possibly unfavorable facts." This paper details a set of techniques to divert attention away from data and towards beauty. Follow these rules faithfully and you'll never need to sully your pretty pictures with the grubby realities of science. May your images be accepted by SIGGRAPH.
